## Crystal Phase Transitions in the Shell of PbS/CdS Core/Shell Nanocrystals Influences Photoluminescence Intensity

Twelve of the 14 individual NC ensembles used for the ASAXS experiments were measured sealed in quartz-glass capillaries of 1. The initial size distributions of 12%, 14%, and 15% for the large, medium, and small NCs is found to be constant within 1%.

Chapter 1 of the installation guide provides some illustrations of possible configurations.

The job will be queued and scheduled as PBS batch job, but when executed the standard input, output, and error streams of the job will be connected through qsub to the terminal session in which qsub is running. This kind of polytypism of crystal phases within one shell was also found for shells grown epitaxial on top of the core.

The shift of the peak positions, especially that of the 220 Bragg peak, where we are most sensitive to changes in the lattice spacings, can be caused by both a different crystal phase and strain effects. We assume for the PbS core always a pure RS structure, but for the CdS-shell either

the RS or the ZB structure. A PbS NC solution, containing 90 mg PbS NCs, was dried, and NCs were redispersed in 5 mL of anhydrous OA.

### **Vidgo Channel List and Packages (2020)**

The replacement of Pb by Cd is achieved by adding an excess of Cd oleate to the PbX NC suspension resulting in a well-defined CdX shell around the PbX core as it was shown for PbSe, PbTe, and PbS. Torque matured into a quality product. A similarly well-defined but much thicker CdS-shell is formed around the medium sized PbS-NCs as shown in Figure c. The vertical dashed lines mark the positions of the Bragg peaks for rock salt RS PbS and zinc blende ZB CdS bulk structures. The indicated distribution of the metastable RS phases within the shell is only a suggestion.
