Also of eminent interest is the construction of SEOF-based stochastic models with predictive capabilities, as suggested early by and demonstrated by and in the context of DAH.

. Barry Simon emphasizes necessary and sufficient conditions, and provides mathematical background that until now has been available only in journals. The session will be focused on existence, bifurcation, multiplicity, localization, stability and approximation of solutions to elliptic or parabolic differential equations studied by means of topological degree, fixed point index, Conley-type indices, fixed point and critical point theories as well as dynamical systems.

In recent years, entropy methods have been successfully extended to cross-diffusion systems, which allowed us to reveal in some cases their formal gradient-flow structure and to develop a global existence analysis.
