OSA

And, we determine the smallest difference such that the two stimuli are just barely discriminable.

Psychophysics of Vision by Michael Kalloniatis and Charles Luu

Sensory-determinacy refers to the absolute magnitude of the threshold.

OSA

However, there are many senses for which the opposite is true: our sensitivity increases as the stimulus increases. The percentage of detection is determined as a function of stimulus intensity. And we count the hits and false alarms to get d' at each light intensity.

Psychophysical methods, or how to measure a threshold, and why

Example: brightness difference threshold experiment where we ask the subject to identify which of two lights is the brighter one.

With both forced choice tracking and PEST, subsequent changes in stimulus intensity relies on the subjects previous two or three responses.
